

Propertypeak Deployment SOP

This document defines the complete, safe, and repeatable deployment workflow for Propertypeak, covering daily work, versioning, rollback, and CI/CD automation.

1. CI/CD Automation

- Code is written only on local machines (VS Code / Antigravity / Trae).
- Deployments are executed automatically by GitHub Actions.
- Developers never SSH into production to deploy code manually.

Staging Deployment

- Trigger: Push to **staging** branch
- Action: Auto-deploy to staging server

Production Deployment

- Trigger: Merge Pull Request into **main**
- Conditions: CI checks + approval required
- Action: Auto-deploy to production server

2. Rollback Strategy

Rollback allows instant recovery if production breaks after a deployment.

Rollback using Git commit

1. SSH into production server
2. Identify last good commit
3. Reset code to that commit

Rollback using version tag (recommended)

- Each production deploy is tagged
- Rollback is done by resetting to the tag

Rollback affects only code. Databases and media remain untouched.

3. Versioned Releases

Every production deployment is assigned a version tag (example: v1.0.2).

Benefits

- Clear history of what is live
- Easy rollback to known-good states
- Professional release tracking

Rule

- No production deployment without a version tag

4. 1-Minute Daily Developer Workflow

Start Work

- Ensure branch is staging

Develop

- Write code locally only

Push

- Commit and push to staging

Verify

- Check staging website

Release

- Create PR: staging → main
- Merge after CI passes
